### ABSTRACT

A dominating set  $D$  of a graph  $G$  is a global cototal dominating set if  $D$  is both a global dominating set and a cototal dominating set. The global cototal domination number  $\gamma_{\text{gcot}}(G)$  is the minimum cardinality of a global cototal domination set of  $G$ . In this paper we determine the value of the global cototal domination number  $\gamma_{\text{gcot}}(G)$  for Friendship graph, Helm graph, Trestled graph, Total graph, Web graph and Grid graph.

Subject Classification: 05C69

### KEYWORDS:

Global domination number, Cototal domination number, Global cototal domination number.

### 1. INTRODUCTION

All graphs considered in this paper are simple, finite, undirected and connected. For graph theoretical terms we refer Harary [6] and for terms related to domination we refer Haynes et al. [7]. A set of vertices  $D$  in a graph  $G$  is a dominating set, if each vertex of  $G$  is dominated by some vertices of  $D$ . The domination number  $\gamma(G)$  is the minimum cardinality of a dominating set of  $G$ . A dominating set  $D$  of a graph  $G$  is a global dominating set if  $D$  is also a dominating set of  $\bar{G}$ . The global domination number  $\gamma_g(G)$  is the minimum cardinality of a global dominating set of  $G$ . This concept was introduced independently by Brigham and Dutton [2] (the term factor domination number was used) and Sampathkumar [11]. A dominating set  $D$  of a graph  $G$  is a cototal dominating set if the induced sub graph,  $\langle V-D \rangle$  has no isolated vertices. The cototal domination number  $\gamma_{\text{cot}}(G)$  is the minimum cardinality of a cototal dominating set of  $G$ . This concept was introduced by Kulli, Janakiram and Iyer in [8]. A dominating set  $D$  of a graph  $G$  is a global cototal dominating set if  $D$  is both a global dominating set and a cototal dominating set. The global cototal domination number  $\gamma_{\text{gcot}}(G)$  is the minimum cardinality of a global cototal domination set of  $G$ . This new concept, the global cototal domination number  $\gamma_{\text{gcot}}(G)$  of a graph  $G$  was introduced by Sheeba Helen and Nicholas in [9]. In this paper we study the minimal condition of a global cototal dominating set and calculate the global cototal domination number in specific classes of graphs.

We need the following.

**Proposition 1.1.[9]** For any complete graph  $K_n$ ,  $\gamma_{\text{gcot}}(K_n) = n$ ,  $n \geq 3$ .

**Proposition 1.2.[9]** For any star graph  $K_{1,n}$ ,  $\gamma_{\text{gcot}}(K_{1,n}) = n + 1$ ,  $n \geq 3$ .

**Proposition 1.3.[9]** For the cycle  $C_n$ ,  $n \geq 6$

$$\gamma_{\text{gcot}}(C_n) = \begin{cases} \frac{n}{3}, & n \equiv 0 \pmod{3}; \\ \left\lceil \frac{n}{3} \right\rceil, & n \equiv 1 \pmod{3}; \\ \left\lceil \frac{n}{3} \right\rceil + 1, & n \equiv 2 \pmod{3}. \end{cases}$$

**Proposition 1.4.[9]** For any wheel  $W_n$ ,  $\gamma_{\text{gcot}}(W_n) = \begin{cases} 4 & \text{if } n = 3; \\ 3 & \text{otherwise.} \end{cases}$

## 2. MAIN RESULTS

### Definition 2.1[9]

A global cototal dominating set of a graph  $G$  is a set  $D$  of vertices of  $G$  such that  $D$  is both global dominating set and cototal dominating set. The global cototal domination number  $\gamma_{\text{gcot}}(G)$  is the minimum cardinality of a global cototal dominating set of  $G$ .

The following theorem of Ore characterizes the minimal dominating sets.

**Theorem 2.2. [10]** A dominating set  $D$  is a minimal dominating set if and only if for each vertex  $v$  in  $D$  one of the following condition holds.

- (i)  $v$  is an isolated vertex of  $D$ .
- (ii) There exists a vertex  $u$  in  $V-D$  such that  $N(u) \cap D = \{v\}$ .

**Theorem 2.3.** A global cototal dominating set  $D$  is minimal if and only if for each vertex  $v$  in  $D$  one of the following conditions holds.

- (i) There exists a vertex  $u$  in  $V-D$  such that  $N(u) \cap D = \{v\}$ .
- (ii)  $N(u) \cap (V-D) \neq \emptyset$ .

**Proof:** Suppose  $D$  is the minimal global cototal dominating set of  $G$ . On contrary if there exists a vertex  $v$  in  $D$  such that  $v$  does not satisfy any of the given conditions, then by the previous theorem,  $D_1 = D - \{v\}$  is a dominating set of  $G$ . By sub division(ii)  $\langle V - D_1 \rangle$  has no isolated vertices. This implies that  $D_1$  is a global cototal dominating set of  $G$  which is a contradiction. Sufficiency is obvious. ■

**Theorem 2.4.** Let  $T$  be the spanning sub graph of a complete graph  $K_n$ , then

$$\gamma_{\text{gcot}}(T) \leq \gamma_{\text{gcot}}(K_n).$$

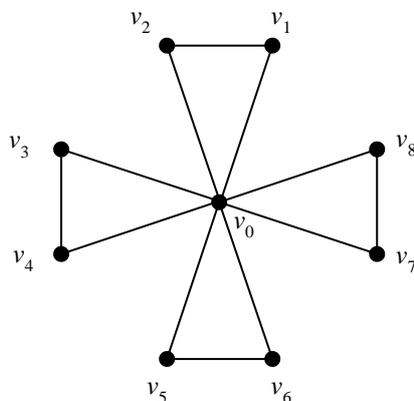

**Proof:** Let  $D$  be the minimal global cototal dominating set of  $K_n$ . Let  $T$  be the spanning sub graph of a  $K_n$ . We know that  $\gamma_{\text{gcot}}(K_n) = n$ ,  $n \geq 3$ , by Proposition 1.1. If  $T$  is a star then by Proposition 1.2 the global cototal domination number of a star graph of order  $n$  is  $n$ . Hence equality holds. If  $T$  is a cycle, by Proposition 1.3 for  $n \geq 6$

$$\gamma_{\text{gcot}}(C_n) = \begin{cases} \frac{n}{3}, & n \equiv 0 \pmod{3}; \\ \left\lceil \frac{n}{3} \right\rceil, & n \equiv 1 \pmod{3}; \\ \left\lceil \frac{n}{3} \right\rceil + 1, & n \equiv 2 \pmod{3}. \end{cases}$$

This proves the theorem ■

**Definition 2.5.** Friendship graph  $C_3^{(t)}$  is a planar undirected graph with  $2n+1$  vertices and  $3n$  edges. It can be got by joining 't' copies of the cycle graph  $C_3$  at a common vertex.

**Theorem 2.6.**  $\gamma_{\text{gcot}}(C_3^{(t)}) = 3$  where t denotes the number of copies of the cycle  $C_3$  identified at a common vertex.

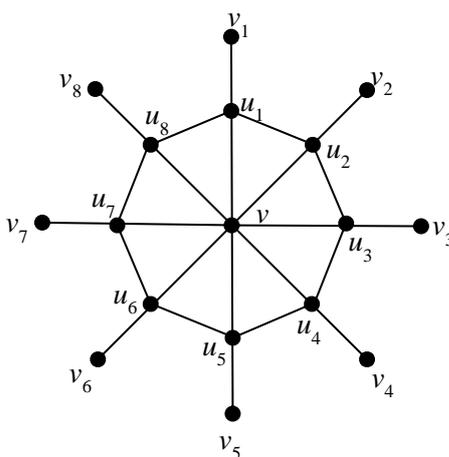

G

Figure 2.4

**Proof:** Let D be the minimal global cototal dominating set of  $C_3^{(t)}$ .  $v_0$  be the apex vertex in  $C_3^{(t)}$ . Then  $v_0$  dominates all other vertices of  $C_3^{(t)}$ . Hence any minimal global cototal dominating set D must contain  $v_0$ . Since  $v_0$  is isolated in  $G^c$ , it does not dominate any vertex in  $G^c$ . Therefore D has a vertex  $v_1 \neq v_0$ . But in this case the sub graph induced by  $\langle V - \{v_1, v_0\} \rangle$  has an isolated vertex  $v_2$  which is adjacent to both  $v_0$  and  $v_1$  in G. Hence  $D = \{v_0, v_1, v_2\} \subseteq V(G)$ . Now D is the minimal global cototal dominating set of  $C_3^{(t)}$  and hence  $\gamma_{\text{gcot}}(C_3^{(t)}) = 3$ . ■

**Definition 2.7.** A graph obtained from a wheel by attaching a pendant edge at each vertex of an n-cycle is a helm and is denoted by  $H_n$ . It is a graph of order  $2n+1$ .

**Theorem 2.8.**  $\gamma_{\text{gcot}}(H_n) = n+1$ .

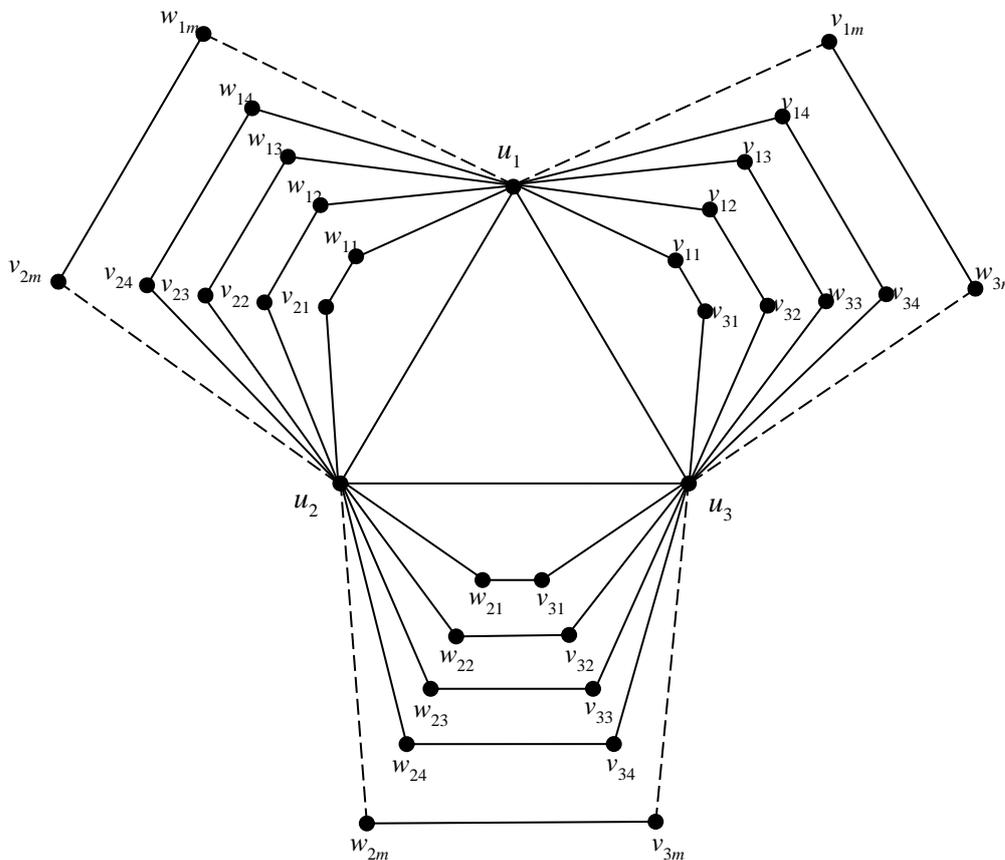

Helm Graph  $H_8$

Figure 2.5

**Proof:** Let  $u_1, u_2, u_3, \dots, u_n$  be the vertices of the cycle. Let  $v_1, v_2, v_3, \dots, v_n$  be the corresponding pendant vertices and  $v$  be the center.  $H_n$  contains  $2n+1$  vertices. Let  $D$  be the minimal global cototal dominating set. Then  $D$  contains  $v$ . Since  $v$  dominates only the cycle vertices  $u_1, u_2, u_3, \dots, u_n$ ,  $D$  must contain a pendant vertex. Then  $D$  must contain all the pendant vertices,  $v_1, v_2, v_3, \dots, v_n \in D$  since otherwise it will violate the cototal property. Hence we claim that  $D = \{v, v_1, v_2, v_3, \dots, v_n\}$  is minimal. The vertex  $v_i$  cannot be replaced with the corresponding  $u_i$ , since otherwise,  $V - \{v, u_1, u_2, u_3, \dots, u_n\}$  induce isolated vertices  $v_1, v_2, v_3, \dots, v_n$  which violates the cototal property. Therefore we choose  $D = \{v_1, v_2, v_3, \dots, v_n, v\} \subseteq V(G)$  as the minimal global cototal dominating set of  $H_n$  and hence  $\gamma_{\text{gcot}}(H_n) = n+1$ . ■

**Definition 2.9.** The trestled graph of index  $k$  denoted by  $T_k(G)$  is a graph obtained from  $G$  adding  $k$  copies of  $K_2$  corresponding to each edge  $uv$  of  $G$  and joining  $u$  and  $v$  to the respective end vertices of each  $K_2$ .

**Theorem 2.10.** If  $G$  is a trestled graph of index  $k$  of a cycle  $C_n$ , then  $\gamma_{\text{gcot}}(G) = n$ .

G

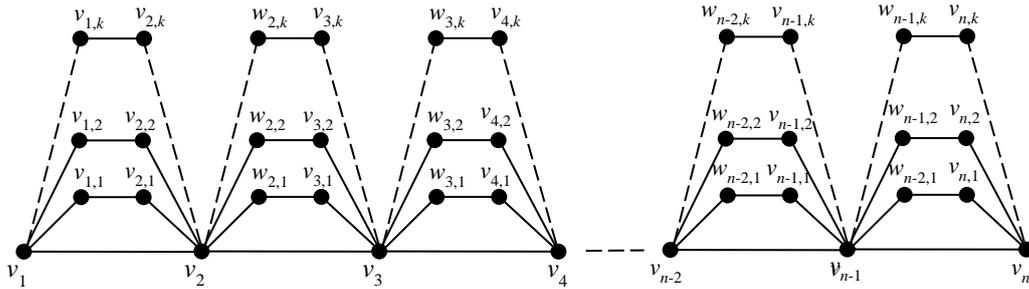

Figure 2.6

**Proof:** Let  $u_1, u_2, u_3, \dots, u_n$  be the vertices of the cycle  $C_n$ . The  $k$  copies of  $K_2$  corresponding to each edge  $u_1u_2$  is labeled as  $w_{11}, w_{12}, w_{13}, \dots, w_{1m}$  and  $v_{21}, v_{22}, \dots, v_{2m}$ . In general  $k$  copies of  $K_2$  corresponding to each edge  $u_iu_j$  ( $1 \leq i, j \leq n$ ) is labeled as  $w_{i1}, w_{i2}, w_{i3}, \dots, w_{im}$  and  $v_{j1}, v_{j2}, \dots, v_{jm}$ . Let  $D$  be the minimal global cototal dominating set of  $G$ . The trestled graph of a cycle  $C_n$  of index  $k$  contains  $n+2kn$  vertices.  $u_i$  is adjacent to  $w_{i1}, w_{i2}, w_{i3}, \dots, w_{im}$  and  $v_{i1}, v_{i2}, \dots, v_{im}$ .

$\dots, w_{im}$  and  $v_{j1}, v_{j2}, \dots, v_{jm}$  of  $k$  copies of  $K_2$  corresponding to each edge  $u_i u_j$  and  $u_i$  is adjacent to the succeeding and preceding vertices  $u_{i+1}, u_{i+2}$  of the cycle. The end vertices of each  $K_2$  is adjacent to the end vertices of each edge  $u_i u_j$  of the cycle. Thus  $D = \{u_1, u_2, u_3, \dots, u_n\} \subseteq V(G)$  is minimal and the induced subgraph  $\langle V-D \rangle$  results in a disconnected graph containing  $nk$  number of  $K_2$ 's. Thus  $D$  is the minimal global cototal dominating set of  $G$ . Hence  $\gamma_{\text{gcot}}(G) = n$ . ■

**Corollary 2.11.** If  $G \cong T_k(C_n)$ , then  $\gamma_{\text{gcot}}(G) = \gamma(G)$ .

**Theorem 2.12.** If  $G \cong T_k(P_n)$ , then  $\gamma_{\text{gcot}}(T_k(P_n)) = n$  for every  $k \geq 1$ .

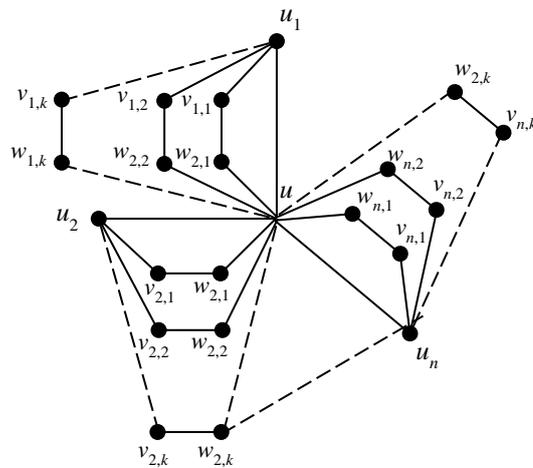

G

Figure 2.7

**Proof:** Let  $v_1, v_2, v_3, \dots, v_n$  denote the vertices of the path  $P_n$ . The initial vertex  $v_1$  of the path  $P_n$  is adjacent to  $k$  vertices namely  $v_{11}, v_{12}, v_{13}, \dots, v_{1k}$  and the end vertex  $v_n$  of the path  $P_n$  is adjacent to  $k$  vertices  $v_{n1}, v_{n2}, \dots, v_{nk}$ . Each internal vertex  $v_i$  of the path  $P_n$  of  $T_k(P_n)$  is adjacent to  $2k$  vertices  $v_{i1}, v_{i2}, \dots, v_{ik}, w_{i1}, w_{i2}, \dots, w_{ik}$ . Then  $|V(T_k(P_n))| = (n-2)(2k+1) + 2k+2 = (2k+1)n - 2k$ . Let  $D$  be the minimal global cototal dominating set of  $T_k(P_n)$ . We have  $\Delta(T_k(P_n)) = 2k+2$ . Since  $\text{deg}(v_i) = 2k+2, (2 \leq i \leq n-1)$ ,  $v_i \in D$ . The induced sub graph  $\langle V-D \rangle$  has  $2k$  isolated vertices  $v_{11}, v_{12}, v_{13}, \dots, v_{1k}, v_{n1}, v_{n2}, \dots, v_{nk}$ . Therefore  $v_1, v_n \in D$ . Thus  $D = \{v_1, v_2, v_3, \dots, v_n\}$  is the minimal global cototal dominating set of  $T_k(P_n)$  with  $|D| = n$ . Hence  $\gamma_{\text{gcot}}(T_k(P_n)) = n$ . ■

**Theorem 2.13.** If  $G \cong T_k(K_{1,n})$ , then  $\gamma_{\text{gcot}}(G) = n+1$  for every  $k \geq 1$ .

G

Figure 2.8

**Proof:** Let  $u$  be the center and  $u_1, u_2, u_3, \dots, u_n$  be the pendant vertices of the star  $K_{1,n}$ . Let  $v_{i1}w_{i1}, v_{i2}w_{i2}, \dots, v_{ik}w_{ik}$  be the edges added to the edge  $uu_i$  of  $K_{1,n}$  as shown in the figure. Let  $D$  be the minimal global cototal dominating set of  $T_k(K_{1,n})$ . The vertex  $u$  dominates  $u_1, u_2, \dots, u_n$  and one end of the edges  $v_{i1}w_{i1}, v_{i2}w_{i2}, \dots, v_{ik}w_{ik}$ . Since the degree of  $u$  is maximum  $u \in D$ . the only possible global cototal dominating sets of  $T_k(K_{1,n})$  are  $D_1 = \{u, v_{11}, v_{12}, v_{13}, \dots, v_{1k}, v_{21}, v_{22}, v_{23}, \dots, v_{2k}, \dots, v_{n1}, v_{n2}, \dots, v_{nk}\}$  with  $|D_1| = nk+1$  and  $D_2 = \{u, u_1, u_2, u_3, \dots, u_n\}$  with  $|D_2| = n+1$ . Since  $|D_2| < |D_1|$  we take  $D_2 = D = \{u, u_1, u_2, u_3, \dots, u_n\}$  as a  $\gamma_{\text{cot}}$ -set of  $T_k(K_{1,n})$  with  $|D| = n+1$ . Also the induced sub graph  $\langle V-D \rangle$  is disconnected containing  $nk$  number of  $K_2$  graphs. Hence  $\gamma_{\text{cot}}(G) = n+1$ . ■

**Definition 2.14.** The total graph  $T(G)$  of a graph  $G = (V, E)$  has vertices that correspond one to one with elements of  $V \cup E$  and two vertices in  $T(G)$  are adjacent if and only if the corresponding elements are adjacent or incident in  $G$ .

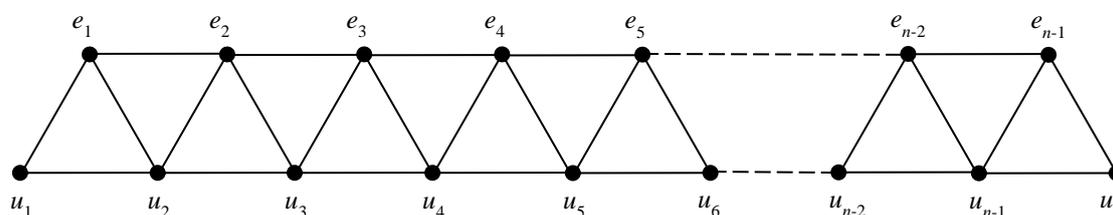

Figure 2.9

**Theorem 2.15.** If  $G \cong T(P_n)$ , then  $\gamma_{\text{cot}}(G) = \left\lceil \frac{2n-1}{5} \right\rceil$ .

**Proof:** Let  $\{u_1, u_2, u_3, \dots, u_n, e_1, e_2, e_3, \dots, e_{n-1}\}$  be the vertex set of  $T(P_n)$  with  $2n-1$  vertices. Let  $D_1$  be the global cototal dominating set of  $T(P_n)$  containing vertices  $u_i, 1 \leq i \leq n$ . Let  $D_2$  be the global cototal dominating set of  $T(P_n)$  containing vertices  $e_i, 1 \leq i \leq n-1$ . Let  $D_3$  be the minimal global cototal dominating set of  $T(P_n)$ . Now let us choose the first five vertices of  $T(P_n)$  say  $e_1, e_2, u_1, u_2, u_3$  here  $u_2$  is adjacent to all the vertices of the above set. Hence  $u_2 \in D_3$ . Similarly for the set of five vertices  $e_i, e_{i+1}, u_i, u_{i+1}, u_{i+2}$  here  $u_{i+1}$  dominates all the other vertices. Hence  $u_{i+1} \in D_3$ . Next we choose the proceeding five vertices of  $T(P_n)$  say  $e_3, e_4, e_5, u_4, u_5$ . The vertex  $e_4$  dominates all the other vertices. Hence  $e_4 \in D_3$ . For the next set of five vertices  $e_i, e_{i+1}, e_{i+2}, u_{i+1}, u_{i+2}$  here  $e_{i+1}$  dominates all the other vertices in the set. Hence  $e_{i+1} \in D_3$ . Proceeding like this we have the remaining vertices as  $i = 0, 1, 2, 3, 4$ . Among these vertices, choose a vertex which is having the maximum degree. Finally we have  $D_3 < D_2 < D_1$  with  $|D_3| = \left\lceil \frac{2n-1}{5} \right\rceil$ .  $D_3$  is a minimal global cototal dominating set with  $|D_3| = \left\lceil \frac{2n-1}{5} \right\rceil$ . Hence  $\gamma_{\text{cot}}(G) = \left\lceil \frac{2n-1}{5} \right\rceil$ . ■

**Definition 2.16.** The web graph is a graph obtained by joining the pendant vertices of a Helm  $H_n$  to form a cycle and then adding a single pendant edge to each vertex of this outer cycle. It is a graph of order  $3n+1$ .

**Theorem 2.17.** For a web graph  $G, \gamma_{\text{cot}}(G) = n+1$ .

**Proof:**  $V(G) = \{u, u_i, v_i, w_i / i = 1, 2, \dots, n\}$  and  $E(G) = \{uu_i, u_iv_i, v_iw_i / i = 1, 2, \dots, n\} \cup \{u_i u_{i+1}, v_iv_{i+1} / i = 1, 2, \dots, n-1\} \cup \{u_n u_1, v_n v_1\}$ . Let  $D$  be the minimal global cototal dominating set. Then  $D$  contains  $u$ , since  $u$  dominates only the cycle  $u_1, u_2, \dots, u_n$ .  $D$  must contain a pendant vertex. Then  $D$  must contain all the pendant vertices  $w_1, w_2, \dots, w_n$  which dominates the vertices of the outer cycle, since otherwise, it will violate the cototal property.

That is  $w_1, w_2, \dots, w_n \in D$ . We claim that  $\{u, w_1, w_2, \dots, w_n\}$  is minimal. The vertex  $w_i$  cannot be replaced with the corresponding  $v_i$ , since otherwise  $V - \{u, v_1, v_2, \dots, v_n\}$  induce a cycle  $C_n$  and isolated vertices  $w_1, w_2, \dots, w_n$  which violates the cototal property. Therefore we choose  $D = \{u, w_1, w_2, \dots, w_n\} \subseteq V(G)$  as the minimal global cototal dominating set of the web graph and hence  $\gamma_{\text{gcot}}(G) = n+1$ . ■

**Definition 2.18.** The Grid graph  $P_m \times P_n$  is the Cartesian product of two paths  $P_m$  and  $P_n$

**Theorem 2.19.** The global cototal domination number of a grid graph is given by

$$\gamma_{\text{gcot}}(P_m \times P_n) = \begin{cases} \frac{mn}{4} + \frac{m}{2} & \text{if } m \text{ is even, } n \text{ is even;} \\ \left\lceil \frac{mn}{4} \right\rceil + \left\lceil \frac{m}{2} \right\rceil & \text{if } m \text{ is odd, } n \text{ is even;} \\ \left\lceil \frac{mn}{5} \right\rceil + \left\lceil \frac{m}{3} \right\rceil + \left\lceil \frac{n}{3} \right\rceil & \text{if } m \text{ is odd, } n \text{ is odd;} \\ \frac{m}{2} \left\lceil \frac{n}{2} \right\rceil & \text{if } m \text{ is even } n \text{ is odd.} \end{cases}$$

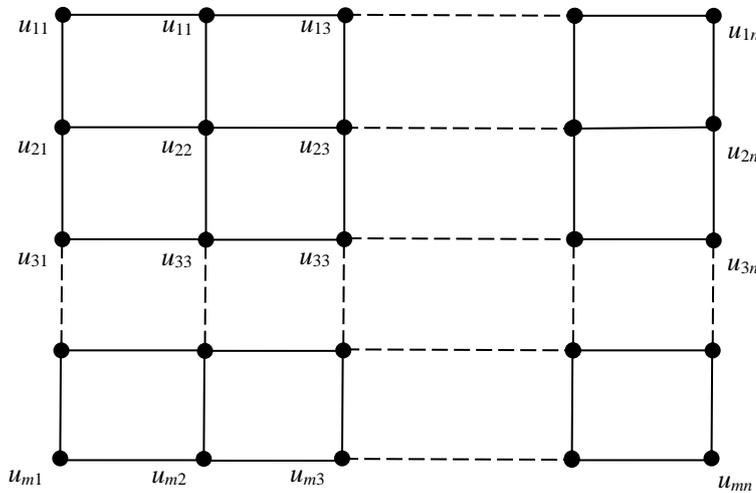

Figure 2.11

**Proof:** Let  $V(P_m \times P_n) = \{u_{ij} / i = 1, 2, 3, \dots, m, j = 1, 2, 3, \dots, n\}$

Consider the following sets

$D_1 = \bigcup_{t=1}^{m/2} \left\{ \bigcup_{s=1}^{\lceil n/4 \rceil} U_{(2t-1)(4s-3)} \bigcup_{s=1}^{\lfloor n/4 \rfloor} U_{2t,(4s-1)} \right\} \bigcup_{t=1}^{m/2} U_{2t,n}$ , where  $m$  is even and  $n$  is even.

$D_2 = \bigcup_{t=1}^{(m+1)/2} \left\{ \bigcup_{s=1}^{\lceil n/4 \rceil} U_{(2t-1)(4s-3)} \bigcup_{s=1}^{\lfloor n/4 \rfloor} U_{2t,(4s-1)} \right\} \bigcup_{t=1}^{(m-1)/2} U_{2t,n}$ , where  $m$  is odd and  $n$  is even.

$D_3 = \bigcup_{t=1}^{m/2} \left\{ \bigcup_{s=1}^{\lceil n/4 \rceil} U_{(2t-1)(4s-3)} \bigcup_{s=1}^{\lfloor n/4 \rfloor} U_{2t,(4s-1)} \right\}$ , where  $m$  is even and  $n$  is odd.

$D_4 = \bigcup_{t=1}^{(m+1)/2} \left\{ \bigcup_{s=1}^{\lceil n/4 \rceil} U_{(2t-1)(4s-3)} \bigcup_{s=1}^{\lfloor n/4 \rfloor} U_{2t,(4s-1)} \right\}$ , where  $m$  is odd and  $n$  is odd.

Consider a 4- square centered at  $u_{ij} \in D$  contains 9 vertices namely  $u_{i-1,j-1}, u_{i-1,j}, u_{i-1,j+1}, u_{i,j-1}, u_{i,j}, u_{i,j+1}, u_{i+1,j-1}, u_{i+1,j}, u_{i+1,j+1}$ . Then  $u_{ij}$  dominates the vertices of  $N(u_{ij}) = \{u_{i,j-1}, u_{i,j+1}, u_{i-1,j}, u_{i+1,j}\}$ . The vertices  $u_{i-1,j-1}, u_{i-1,j+1}, u_{i+1,j-1}, u_{i+1,j+1}$  are dominated by  $u_{i-1,j-2}, u_{i-1,j+2}, u_{i+1,j-2}, u_{i+1,j+2}$  respectively. Hence  $D$  is a dominating set of  $P_m \times P_n$ . Obviously  $D$  dominates  $G^c$ .

Moreover  $V(G) - D$  induces a subgraph containing paths  $P_m$ 's and  $P_3$ 's and no isolated vertices. Hence  $D$  is a global cototal dominating set of  $P_m \times P_n$ . Let  $x \in D$ . Suppose we

remove  $x$  from  $D$  the vertex  $x$  is not even dominated by any of the vertices of  $D$  since  $D$  is an independent set.

Hence  $|D_1| = \frac{mn}{4} + \frac{m}{2}$ , if  $m$  is even,  $n$  is even.

$|D_2| = \left\lfloor \frac{mn}{4} \right\rfloor + \left\lfloor \frac{m}{2} \right\rfloor$ , if  $m$  is odd,  $n$  is even.

$|D_3| = \frac{m}{2} \left\lfloor \frac{n}{2} \right\rfloor$ , if  $m$  is even,  $n$  is odd.

$|D_4| = \left\lfloor \frac{mn}{5} \right\rfloor + \left\lfloor \frac{m}{3} \right\rfloor + \left\lfloor \frac{n}{3} \right\rfloor$ , if  $m$  is odd,  $n$  is odd. ■
