

NEW ALGORITHM FOR RANKING RESEARCH PAPERS BASED ON CITATION NETWORK AND PERFORMANCE

Mr. Bineet Gupta *

Dr. Prashant Kumar Pandey**

Abstract:

In this paper we propose an efficient method to rank the research papers from various fields of research published in various conferences over the years. This ranking method is based on citation network. The importance of a research paper is captured well by the peer vote, which in this case is the research paper being cited in other research papers. Using a modified version of the PageRank algorithm, we rank the research papers, assigning each of them an authoritative score. Using the scores of the research papers calculated by above mentioned method, we formulate scores for conferences and authors and rank them as well. We have introduced a new metric in the algorithm which takes into account the time factor in ranking the research papers to reduce the bias against the recent papers which get less time for being studied and consequently cited by the researchers as compared to the older papers. Often a researcher is more interested in finding the top conferences in a particular year rather than the overall conference ranking. Considering the year of publication of the papers, in addition to the paper scores we also calculated the year wise score of each conference by slight improvisation of the above mentioned algorithm.

Keywords - Ranking, Citation Network, Authoritative Score

I. INTRODUCTION:

Thousands of research papers are published every year and these papers span various fields of research. For a new researcher, it becomes a very difficult task to go through the entire repository of research papers in order to determine the *important* ones. The term *important* is subjective but it can be assured that a research paper that is popular will be *important* in most cases. There can be several ways of determining whether a research paper is *important* depending on the field of work, conference of publication, etc.

In this paper we propose an efficient method to rank the research papers from various fields of research published in various conferences over the years. Our method is based on the citation network of the research papers. Research papers cite other research papers from which they derive inspiration and there exists a well connected graph structure among the network of research papers. The importance of a research paper is directly proportional to the number of research papers that cite it. We have used this concept in our algorithm. Often a researcher might be more interested in knowing about the *important* conferences and authors from the field of his/her research. Using the research paper scores as determined by our algorithm, we formulate the conference scores. A conference is as good as the research paper that it publishes. We have used this notion to rank the conferences based on the quality of research papers published by them. For an author, not only the quality of research paper published by him/her but also the quality of conference in which he/she publishes the paper is important. So for the author scores, we use both the research paper scores and the conference scores for all the research papers published by the authors. A system ranking research papers, conferences and authors can have various applications. Some straightforward uses can be:

- Looking up the quality of a given research paper
- Comparing two or more research papers
- Comparing the research papers published in a given year
- Comparing the research papers published at a conference
- Comparing two or more conferences
- Comparing the quality of a conference as years pass
- Comparing two or more authors

- Comparing the research papers by a particular author

II. RELATED WORK:

There has been considerable work in the field of academic research. Most of the work is on researcher profiling, which aim at ranking the authors. The work by Quinkun Zhao et al. [9] is one such work, which studies the relationship between authors using community mining techniques. Other work is ArnetMiner [8] which ranks the authors on h-index [5] and conferences on impact factor [4]. Our main focus here is to rank the research papers.

The rankings for conferences and authors are derived from the research paper ranks. Most work on academic research uses number of citations as the metric. However, it is quite intuitive that this metric ignores the importance of the quality of citations, taking into consideration only the quantity of citations. The metrics like h-index, g-index and impact factor are based on the number of citations, and hence would not give correct results in all cases. We use a modified version of the PageRank algorithm [7], which considers the quality of the citing paper to rank the paper being cited. Also, unlike in h-index, here we need not remove the self-citations because our main focus is ranking research papers. Author ranking is taken care of by the research paper scores. The metric impact factor has another drawback that it uses only the citations from only the last two years, which simply neglects the effect of papers on comparatively older papers that they cite. It is to be noted that the metrics based on number of citations are highly discipline-dependent. This effect is diminished by the fact that if a field has more number of citations in general than the other fields, the division by number of citations during contribution of a citing node works in the same way as normalization works.

There has been some work on academic research using PageRank algorithm like the work by Ying Ding et al. [3], where author co-citation network is used to rank the authors. Rest of the paper is organized as follows: Section 3 describes our ranking algorithms. Section 4 presents the experiments and results. Section 5 talks about some applications of our algorithms and section 6 concludes our work.

III. OUR APPROACH:

Our method is entirely based on the graph structure of the citation network formed by the research papers.

Definition 1. Citation Graph: We define the citation graph $G = (V, E)$ comprising a set V of nodes, which each node N_i representing a research paper R_i and a set E of directed edges, with each edge E_j directed from the citing node N_i to the cited node N_j . We will build the citation network defined as a graph, with each research paper representing a node and the citations representing the edges in the graph, the edges being directed ones, directed from the citing node to the cited node. Each node has several attributes viz. research paper title, author(s), year of publication and conference of publication.

A. **The Ranking Algorithm**

The algorithm for ranking the research papers based on citation network uses the two types of edges in a graph:

Definition 2. Outlinks: From a given node N , link all the nodes N_i that the node N cites.

Definition 3. Inlinks: To a given node N , link all the nodes N_j that cite the node N . These outlinks and inlinks will be used while calculating the authoritative score [6] for each node. The algorithm for ranking the research papers consists of two parts:

- Creating the outlinks and the inlinks.
- Using modified iterative PageRank algorithm to calculate the authoritative score for each node.

The above two parts are implemented by the following two procedures.

Procedure 1: Create Outlinks and InlinksRequire: Paper Citation PC

```

1: Paper Outlinks  $PO = PC$ 
2: for each paper  $P$  in  $PO$ 
3:   Citations List  $CL = PC[P]$ 
4:   Outlinks Count  $OC[P] = CL.length()$ 
5:   for each citation  $C$  in  $CL$ 
6:     if  $C$  in  $PI$ 
7:       append  $P$  to  $PI[C]$ 
8:     else
9:        $PI[C] = [P]$ 

```

The procedure 1 uses paper citations and creates a data structure mapping each paper to its inlinks and outlinks.

In the procedure, we first determine the list of all the papers a paper cites (Step 3). Corresponding to each paper, the number of outlinks is stored in OC (Step 4). Then from step 5 to step 9, we form the data structure to store the inlinks corresponding to each paper.

Procedure 2: Modified Iterative PageRank AlgorithmRequire: Citation Network CN , Paper Year PY , Outlinks Count OC , Paper Inlinks PI , Damping Factor θ

```

1: Initialize Paper Rank  $PR$  to 1.0 for each paper  $R$ 
2: while true
3:    $flag = true$ 
4:   for each paper  $R$  in  $PR$ 
5:     Current Score  $CS = PR[R]$ 
6:     if  $R$  in  $PI$ 
7:       Inlinks List  $IL = PI[R]$ 
8:       New Score  $NS = 0.0$ 
9:       for each inlink  $I$  in  $IL$ 
10:        if  $I$  in  $PR$ 
11:           $NS += PR[I]/OC[I]$ 
12:         $NS = (1-\theta) + \theta * NS$ 
13:        if  $CS$  is not equal to  $NS$ 
14:           $flag = false$ 
15:          Updated Paper Rank  $UPR[R] = NS$ 
16:   if  $flag$  is equal to true
17:     break
18:   copy  $UPR$  to  $PR$ 
19:   clear  $UPR$ 
20: Maximum Score  $MS = \text{Maximum Score in } PR$ 
21: for each paper  $R$  in  $PR$ 
22:    $PR[R] /= MS$ 

```

The procedure 2 is essentially a modified version of the iterative PageRank Algorithm. The iterative PageRank algorithm starts with initializing all the candidates to a constant value,

generally unity and then it iteratively modifies each candidate's score depending on the score of the candidates that point towards it. It stops when all the candidate scores converge, i.e. become constant. Step 1 initializes the score of each paper to unity. Step 2 to 19 is the iterative calculation of the authoritative score for each paper. The iteration stops when there is no change in the score of any paper during the iteration. This is signified by no change in value of flag set to true in step 3; flag is set to false in step 13 and 14 if there is a change in the score of any paper during the update step. From step 4 to 15, for each paper, a new authoritative score is calculated based on the scores of the inlinks in the previous iteration (Step 9 to 11). The PageRank algorithm is based on the fact that the quality of a node is equivalent to the summation of the qualities of the nodes that point to it. In this case, quality refers to the score of the research paper. Now if a research paper cites more than one research paper, it is obvious that it has drawn inspiration from various sources and hence its effect on the score of the paper it cites should diminish by a factor equal to the number of paper it cites. This fact is used in step 11 by dividing the inlink score by the number outlinks of the inlink. *Step 12* modifies the score calculated above to incorporate the damping factor. The use of damping factor is required to prevent the scores of research papers that do not have any inlinks from falling to zero. The value of damping factor is set to 0.85 [1].

The formula for calculating the score at a given iteration is:

$$NS = 0.15 + 0.85 * \sum (PR[I]/OC[I])$$

In step 20 to 22, we normalize the scores to scale down the scores within the range [0, 1]. Thus, finally we get the authoritative scores of each research paper based on the score of the research papers that have cited it.

The above algorithm is fairly sufficient for ranking the research papers. But there is one important aspect that has not been considered yet – time. It is quite obvious how time is a very important factor when it comes to ranking the research papers. The older research papers obviously have more time to be studied by the researchers all over the world and consequently be cited in various research papers. The newer ones fall behind in this aspect. To make our algorithm time-independent, we need to have some normalization of the scores based on time. B.

Time-independent Scoring To make the algorithm time-independent, we need a time-dependent metric that can be used in our formula for the authoritative score in the algorithm. The metric we propose to use is the Average Number of Citations per

Paper in a year, i.e. the average of the total number of citations of the research papers published in each year. This metric is suitable for normalization with respect to time as it captures the fact that an older paper has more time to be cited by researchers in comparison to the recent papers.

We need to modify the formula for calculation of NS in the procedure 2, to incorporate time-independence. For each research paper, we have the year of its publication. Using the year of publication of all the research papers, we will pre-compute the total number of citations for each year and the number of research papers published in each year. Using them, we will determine the average number of citations per paper for each year. The following pseudo-code needs to be added to the procedure 2, before step 1.

```

0a: for each paper R in PY
b:   year Y = PY[R]
c:   Year Citation Count YCC[Y] += OC[R]
d:   Year Paper Count YPC[Y] += 1

e: for each year Y in YCC
f:   Average Year Citations Count AYCC[Y] = YCC[Y]/YPC[Y]

```

Once we have the average number of citations per year, we need to modify the formula for calculating the authoritative score. We will simply divide the NS by the average number of citations in the year of publication of the paper concerned. The change required in procedure 2 is in step 12:

```

12a:   year Y = PY[R]
b:     NS = (1-θ) + θ*NS/AYCC[Y]

```

C. Ranking Conferences

The rank of a conference depends on the quality of research papers it publishes. This is the key idea behind our algorithm for ranking conferences. Using the authoritative scores for the research

papers, we will rank the various conferences by calculating a cumulative authoritative score for each conference. The score for a conference will essentially be the average score of all the research papers published in that conference. The formula for the score of a conference is:

$$\text{Conference Score } CS = \Sigma(\text{Paper Score } PS) / (\text{Number of Papers published in the Conference } NPC[C])$$

An extension of the ranking of the conferences is ranking the conferences year-wise and not as a whole. For example, we might want to know whether VLDB1990 was better than SIGMOD1992 in terms of the quality of research papers published or was it vice-versa or we might want to know how the quality of research papers published in KDD is varying over the years. For this, we need to make a small change in the way the conference score is being calculated. Earlier we used just the conference name as the key for scoring the conference score. Now we concatenate the year of publication to the conference of publication to the conference name and use this concatenated term as the key. Thus we have keys based on year-wise granularity like KDD1999, ICDE1991, etc.

The formula for the score of the conference remains the same:

$$\text{Conference Yearwise Score } CIS = \Sigma(\text{Paper Score } PS) / (\text{Number of Papers published in the Conference in a given year } NPCI[C][Y])$$

D. Ranking Authors

The rank of an author depends not only on the quality of research papers but also the conference he/she publishes his/her papers in. For ranking authors, thus we will use the scores of the research papers published by the author as well as the score of the conference in which the paper was published. This would incorporate the fact that publication in a comparatively better conference is more difficult. The authoritative score for the authors thus is essentially a weighted mean of the scores of the research paper the author has published, with the score of the conference as the weight. The formula for the score of an author is:

$$\text{Author Score} = \frac{\sum(\text{Paper Score } PS * \text{Conference Score } CS)}{(\text{Number of Papers published by the Author } NP_{i[A]})}$$

IV. EXPERIMENTS AND RESULTS:

A. Dataset

For building the citation network, we used the *DBLP XML Records* available at <http://dblp.uni-trier.de/xml/> [2]. The DBLP dataset contains information about various research papers from various fields published over the years. This information includes the name of the research paper, its author(s), the year of publication, the conference of publication and the list of research papers the given research paper cites. We built the citation network defined as a graph, with each research paper representing a node and the citations representing the edges in the graph, the edges being directed ones, directed from the citing node to the cited node. Each node is uniquely represented by the unique key from *DBLP* and the node has several attributes viz. research paper title, author(s), year of publication and conference of publication. It is to be noted that the *DBLP* dataset that we used contained citation information till the year 2010 only.

B. Data Pre-processing

The DBLP dataset also contains information that is not useful in our algorithms. We need pre-process the dataset to extract only the information that we will use in our algorithms. In data pre-processing, we extracted all the titles, author(s), conference of publication, year of publication and citations.

C. Results

We implemented our algorithms on the DBLP dataset and discovered various interesting results. The DBLP dataset contains 16,32,442 research papers from the various fields of research and published in various conferences all over the world. The iterative modified PageRank algorithm converges in 212 iterations for the DBLP dataset in the time dependent domain and in 32 iterations in the time independent domain. This shows that the time independent algorithm converges faster than the time dependent algorithm. This is because the authoritative scores of

the papers are more uniform in the time independent domain due to the normalization by Average Number of Citations per Paper. The ranked list of research papers, conferences and authors produced by our experiments were verified and found to be reasonably good by the field experts.

C.1. Ranking Research Papers

The following tables show the top 10 research papers as determined by our algorithm for ranking the research papers, in time-dependent and time-independent domains.

TABLE I. TOP 10 PAPERS IN TIME-DEPENDENT DOMAIN

Title	Score
<i>Computers and Intractability: A Guide to the Theory of NP-Completeness.</i>	1.00000000
<i>A Relational Model of Data for Large Shared Data Banks.</i>	0.71658114

V. APPLICATIONS:

As mentioned earlier, our algorithms have a variety of applications in various fields of research, using the scores and ranks calculated by our algorithms. A. Ranking Keywords (Theme Mining) An important application of such a system is in the area of theme mining. Given a research paper, we can very well find out the keywords that the research paper is based on. Thus we can cluster research papers on the basis of their keywords. Now we simply need to iterate over the keywords and find the average score of the research papers that contain that keyword. This would be the authoritative score for that keyword.

$$\text{Keyword Score } KS = \sum(\text{Paper Score } PS) / (\text{number of research paper based on the keyword } NP[K])$$

Using a technique similar to that used for ranking conferences on year wise granularity, we can rank the keywords on year wise granularity as well.

$$\text{Keyword Yearwise Score } KSY[Y] = \sum(\text{Paper Score } PS) / (\text{number of research paper published in a given year based on the keyword } NPY[K][Y])$$

Now having the keywordYearwiseScore, we can select say the top ten keywords for each year and call that the major theme of research for that year.

B. Speculative Ranking

For a newly published research paper, we can devise a formula based on the citation network of the author(s) and the authoritative score of the conference in which the paper is published. Thus, we can incrementally add newly published research papers to the ranking system.

VI. CONCLUSIONS AND FUTURE WORK:

The purpose of our work was to propose a way to identify the key research papers, conferences and authors from various fields of research. We have proposed a new and efficient method to achieve this cause. We introduced the time-independent algorithm for ranking, which as shown gives fairly satisfactory results. We analyzed the results and did a comparative study based on the ranking obtained by our algorithms. The above work has a host of new areas of implementation. As mentioned above, we would like to implement theme mining on the keywords based on the ranking of the research papers. This can be extended to keywords in conferences, which could help new researchers to identify the conferences of his/her interest. Similarly we can also extend this work to keywords by authors. Another future work can be the implementation of our work in recommendation systems. We can have a system identifying co-authors and recommending topics of interest, etc.
